HTML & CSS

Week 4: Layout Techniques

Layout Techniques

HTML without CSS will display information from left to right and top to bottom.

CSS provides properties that allow you to set up the lay out of your page

01

Positions

Location and spacing for elements on a page

position: static

Example: {

```
    position: static;  
}
```

The default position for elements

position: relative

Example: {

```
    position: relative;  
    top: 120px;  
}
```

Can position elements relative to its default page

Paired with offset properties

top - moves element down from top

bottom - moves element up from bottom

left - moves element to the right

right - moves element to the left

z-index

Example: {

```
    position: relative;
```

```
    z-index: 1;
```

```
}
```

Controls how forward or back (depth) an element appears when it overlaps relative to other elements.

Can be used with relative but not with

position: absolute

Example: {

```
    position: absolute;  
    width: 100%;  
}
```

The other elements in the page will function as if the element is not there.

The absolute element will position itself relative to its closest element. Position can be modified with offset properties.

position: fixed

```
Example: {  
    position: fixed;  
}
```

Fixed an elements to a specific position on the page and will remain on the page when scrolling

Position defined by offset property

top - moves element down from top

bottom - moves element up from bottom

left - moves element to the right

right - moves element to the left

position: sticky

```
Example: {  
    position: sticky;  
    top: 100px;  
}
```

Similar to fixed, when scrolling it will remain on the page but the defined offset properties make it stick to that position on the page.

Ex: the image will stick to the the position until you reach 100px from the top then it will be free to scroll

02

Display

display: block

Example: `<h1><h2>`

Block elements always start a new line. They modify the full width. Ex: `<h1>`, `<div>`

Some examples of block elements:

https://www.w3schools.com/html/html_blocks.asp

display: inline

Example:

HTML `<inline element>Welcome</inline element>`

```
CSS {  
    display: inline  
}
```

Modifies their particular content and only takes up as much space as its contents take up. It does not start a new line

Some examples of inline elements:

https://www.w3schools.com/html/html_blocks.asp

display: inline-block

Example: {
 display: inline-block;
}

Combining both elements inline-block features can appear next to each other and can be defined by width and height .

03

Others

Float and Clear

float

```
Example: {  
        float: right;  
    }
```

Image-halo text wrap

This is a block of text that will appear on my website. It will wrap around images. This is a block of text that will appear on my website. It will wrap around images. This is a block of text that will appear on my website. It will wrap around images. This is a block of text that will appear on my website. It will wrap around images. This is a block of text that will appear on my website. It will wrap around images. This is a block of text that will appear on my website. It will wrap around images. This is a block of text that will appear on my website. It will wrap around images. This is a block of text that will appear on my website. It will wrap around images. This is a block of text that will appear on my website. It will wrap around images. This is a block of text that will appear on my website. It will wrap around images.

Can move elements as far left or right as possible in its content container. Ex: wrapping text around an image. Must have a specified width otherwise there will be no visible results.

Float values:

right - moves elements as far right as possible

left - moves elements as far left as possible

clear

```
Example: {  
    clear: right;  
}
```

Controls the flow next to floated elements to avoid overcrowding between elements in the same container and specifies what should happen next to the floated elements

Values:

left - left side will not touch any other elements

right - right side will not touch any other elements

both - neither side of elements can touch other elements

none - elements can touch either side

04

Flexbox

Layout that distributes space between items and allows for several types of alignments

1. Flexbox container

Example:

```
<div class= "flexbox_container">  
  <div>1</div>  
  <div>2</div>  
  <div>3</div>  
</div>
```

Create a flexbox container with items
inside . Set a overall class

2. Flex display properties

```
Example: {  
    display: flex;  
    flex-direction: row;  
}
```

Set display to flex so the container can be modified.

Then you define specific flex properties:
Flex Display Properties

CSS Flexbox

flex-direction

row

column

row-reverse

column-reverse

align-items

flex-start

center

flex-end

stretch

justify-content

flex-start

center

flex-end

space-between

space-around

space-evenly

align-content

flex-start

center

flex-end

stretch

space-between

space-around

3. Flex Item properties

Example: `<div style= "[item property]" > 1</div>`

Now you can modify the individual elements with flex item properties in HTML code using `style= ""`

Flex Item Properties
